

Validation of OMPS LP v2: TH correction and time dependent variability

Natalya Kramarova, P.K. Bhartia, Leslie Moy

Outline:

TH correction for version 2:

1. Do we see improvement due to latitudinal TH correction?
2. Do we see evidence of 100m step in ozone data?

What have left after TH correction?

Simple TH correction

Largest TH change for equatorial (100m) and northern latitudes (150-200m) occurs in period from April 2012-April 2013

For South Pole latitudes the largest change occurred after April 2013

Mean ozone profiles, May 2012/2013, 47N

Differences

Mean ozone profiles, Oct-Nov 2013, 80S

Differences

Mean ozone profiles, July&October 2012, EQ

Differences

Sensitivity to
TH correction

Biases relative to MLS before (solid lines) and after (dashed lines) TH correction

Biases between LP and MLS/ACE, April 2012 – March 2013

No TH corrections

OMPS LP v2 against lidars

No TH correction

Central slit

This slope indicates possible TH error

OMPS LP v2 against lidars

Simple TH correction

Central slit

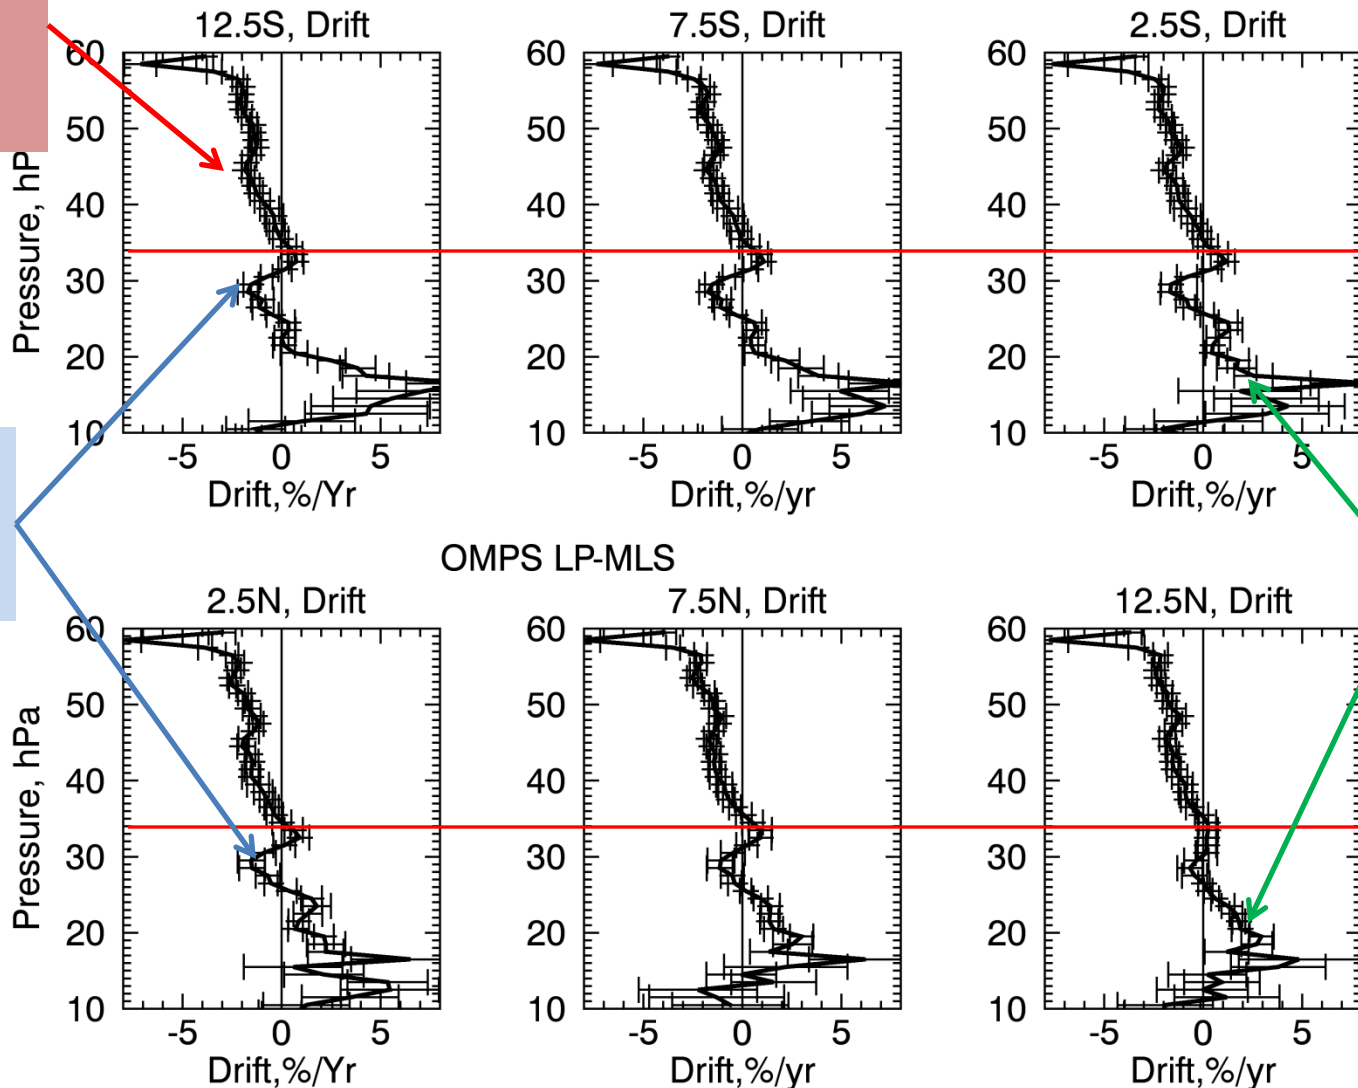

The slope reduced after TH corrections

Drift between LP v2 and MLS

There is a negative drift above 35 km

At ~35 km drift between LP and MLS close to 0

Below 25 km drift is mostly positive

35 km

Negative drift around 30 km;

Drift between LP v2 and MLS

Ozone number density @45km

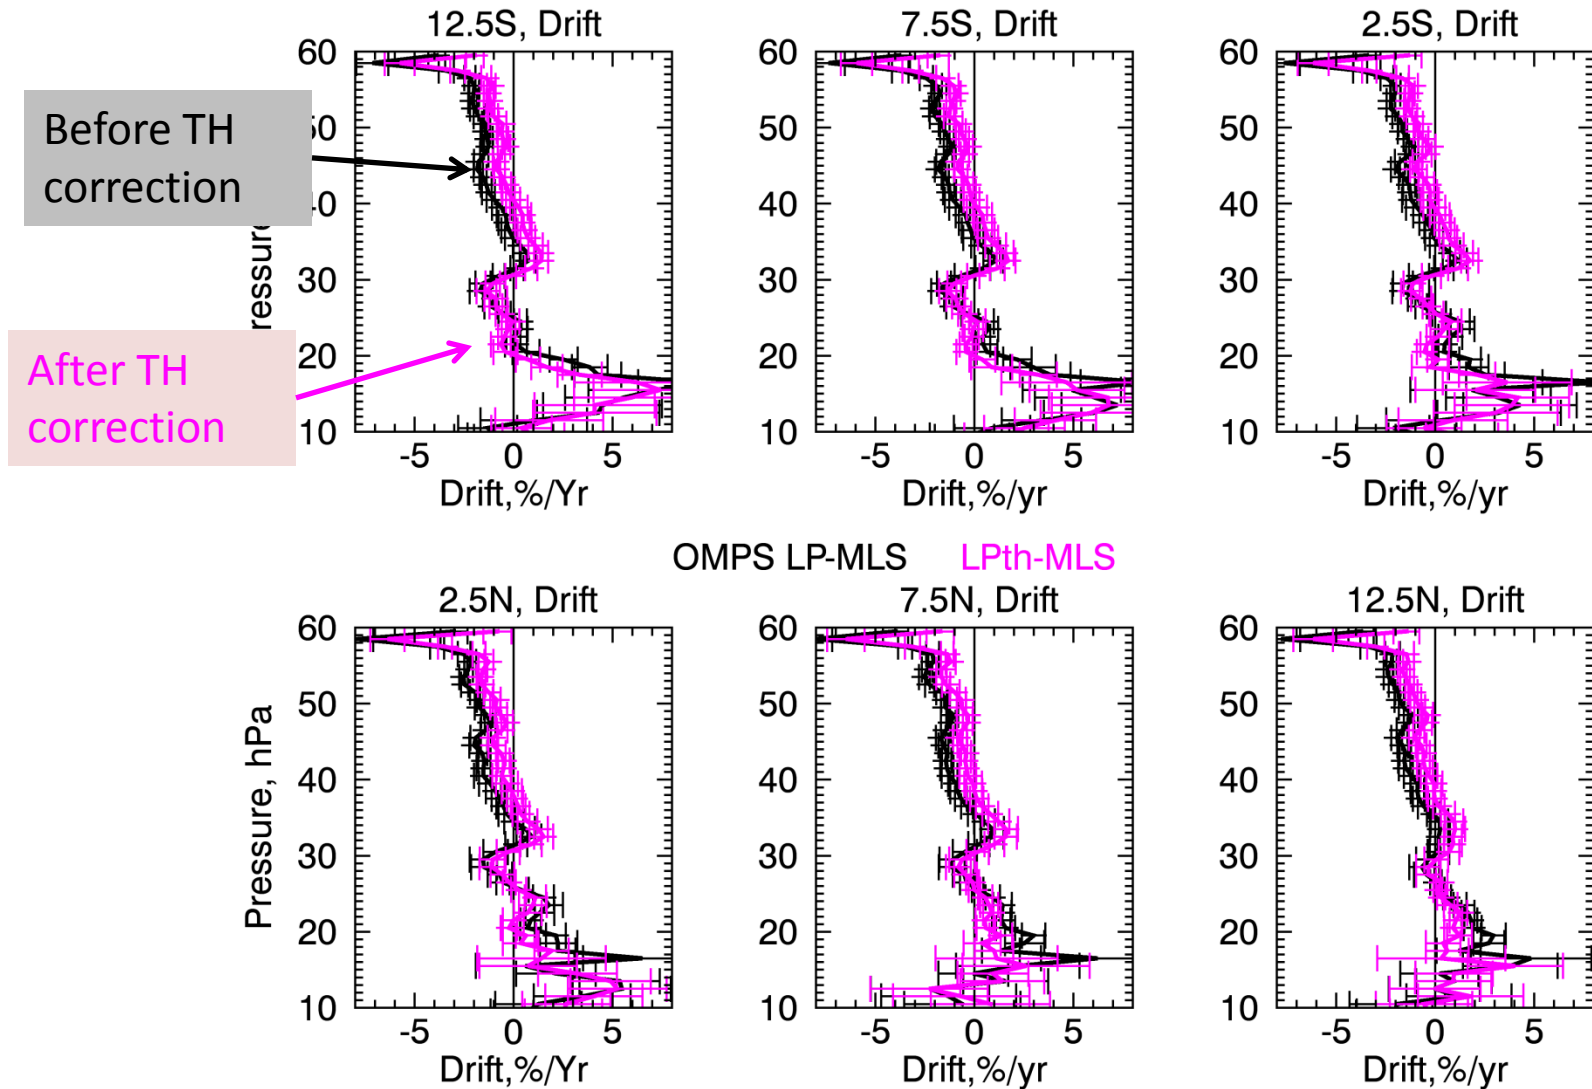

Drifts do not depend on latitude above 35 km

Trends derived from LP and MLS have clear latitudinal structures, which are similar for both instruments

Jan 2012-Dec 2015 MLS/N19 Anomaly Drift

Does the TH correction helps to reduce drifts?

Is the linear fit a good tool to determine drifts ?

Time series of LP and MLS @ 40 km, Tropics

Time series of LP and MLS @ 40 km, NH

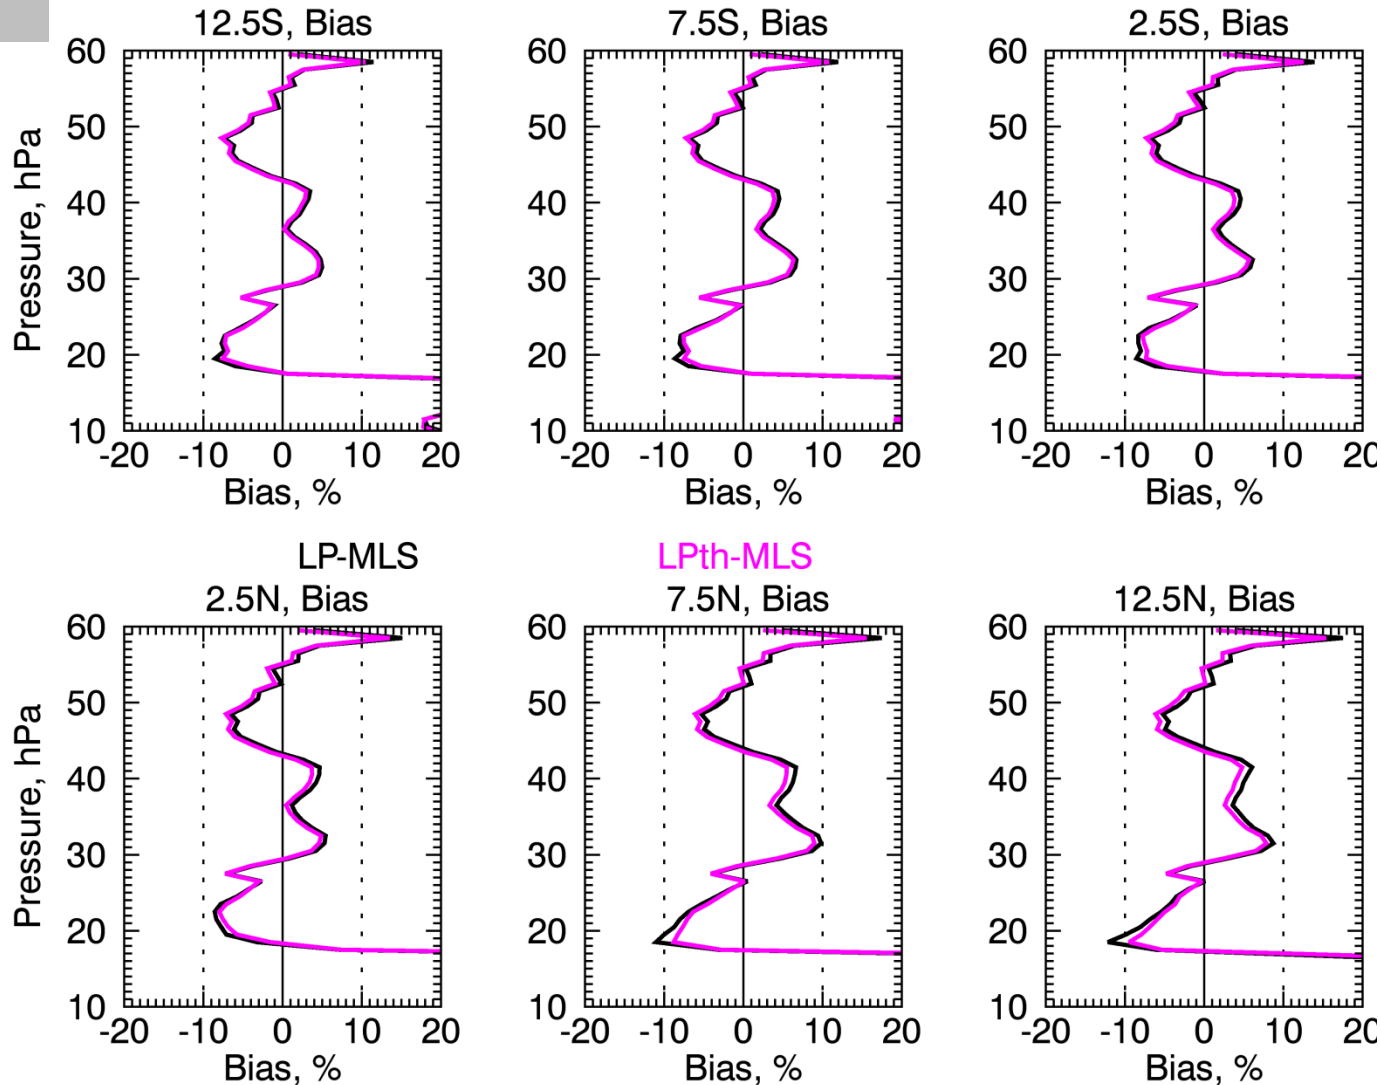

Time series of LP and MLS @ 40 km, SH

Does TH correction change the structure of LP-MLS biases over the entire 3-year period?

Tropics

Does TH correction change the structure of LP-MLS biases over the entire 3-year period?

NH mid-latitudes
